021
      )
022
023
     (return result)
024
025 )
026)
```

Here's a description of the above program:

- 000: This line has a comment on it, indicated by the #
- 001: Defines a class called main; all Brewin programs must have a main class. When the Brewin interpreter runs a program, it first instantiates an object of the main class's type and then executes the main method within this object.

- 003: This defines a member variable (a "field") named num whose initial value is 0. In Brewin v1, fields are not given fixed types, is in (++5.4) are noticed that there refer to values of different types over time.
- 004: This defines a member variable (a "field") named result whose initial value is 1. All Brewin fields
- 007: This defi of our main class. Execution of a Brewin program starts with many and the starts with the start with
- 008: This is a pegin statement allows you to sequence one or more nested statement allows you to sequence one or more up of a single to the period of the period of the pegin statement allows you to sequence one or more upon a single to the pegin statement allows you to sequence one or more upon a statement allows you to sequence upon a statement allo
- 009: This statement prints data to the screen.
- 010: This statement inputs an integer (hence "inputi") from the keyboard and stores it into the member variable harded nuce. Stutores
- 011: This statement prints something like "5 factorial is 120" to the screen. To get the factorial result, it makes a method call to the factorial method within the "me" object.

 "me" is like "this in C++ or radiffice within Refers to the current object.
- 014: This defines the "factorial" method in our main class. You can see that the factorial method accepts one parameter called n. Parameters in Browin v1 don't have types specified for them, meaning that be doubt refer to different types of values depending on what values are passed in over time.
- 015: The begin statement lets us run multiple statements in the factorial function.
- 016: The set command sets the akie of the merther variable result to 1.
- 017: This is a while loop which will continue running while n > 0.
- 018: The begin statement lets us run multiple statements in the while loop. The body of a while loop must be a single statement, so adding a begin statement lets us run multiple sub-statements in the while loop. The body of a while loop must be a single statement, so adding a begin statement lets us run multiple sub-statements in the while loop. The body of a while loop must be a single statement, so adding a begin statement lets us run multiple sub-statement lets us run multiple sub-statement.
- 019: Sets the value of the result member variable to n * result.
- 020: Decrements the value of the member variable n.
- 023: Returns the value of the result member variable as the result of the factorial function.

Let's distill some interesting facts about the Brewin v1 language that we can glean from our program:

Formatting:

- Brewin requires that statements be enclosed in parentheses like LISP. You must have the right number of parentheses or your program won't work! Too many or too few can cause problems, so be careful!
- o Comments in Brewin begin with a # sign.
- Spaces and newlines are used as separators there are no parentheses, commas, semicolons, etc.

Classes:

- Our program contains a simple classicalled "main" in highes residuately in all Brewin programs), but a Brewin program can have additional classes if you like.
- Before execution begins, the Interpreter instantiates a "main" object based on the definit
- Once en instantiated, the Interpreter then asks that object to run en a secure secure

Variables:

- There ables in Brewin v1 member variables (aka fields) in classe functions. There are no local variables in Brewin v1, other t
- Fields (aka member variables)
 - Fields are defined with a "field" keyword in a class.
 - Tour don't specify types for field variables. So field variables don't have excepted by the values they be to so have types. Thus a member variable may refer to values of different types over time, just like in Python.
 - Aessignment Project Exam Help
 - All fields must have a constant value specified for their initial value.
 - All fields in an object are private and may only be accessed by methods in the same object.

Parameter narables: tutores @ 163.com

- Parameter variables are defined in a method's prototype.
- Parameter variables are typeless (so you can pass different types of vales each time of parameter variables are typeless (so you can pass different types of vales each time of parameter variables are typeless (so you can pass different types of vales each time of parameter variables are typeless (so you can pass different types of vales each time of parameter variables are typeless (so you can pass different types of vales each time of parameter variables are typeless (so you can pass different types of vales each time of parameter variables are typeless (so you can pass different types of vales each time of parameter variables are typeless (so you can pass different types of vales each time of parameter variables are typeless (so you can pass different types of vales each time of parameter variables each time of
- Parameter variables can have their value changed.
- All variables are assigned via the "set" statement.

Methods:

- o All methods within a class are defined of the method" keyword.
- All methods in a class are public.
- The main method, within the main class, is a special method where execution of a Brewin v1 program begins.
- Methods may have zero or more parameters, which are specified in parentheses right after the method name. So the main method has no parameters, and the factorial method has a single parameter called n.
- Every method must have a single top-level statement as its body, e.g., (print "hello world"). If you want to run more than one statement in a method, you must make the top-level statement in the method a "begin" statement which can have one or more sequenced sub-statements, e.g.:

```
# every method has a single statement
(method talk () (print "hi there"))

(method greeting ()
```

(begin # the method's single statement is a begin statement

recompthen semente multiple sophin timenting nere begin

(print "hello ")

(print "world")

All me the call keyword. When you use the call keyword, you me the call keyword is being directed to, then the method to be called the call of the method. So the

(call me factorial num)

calls the factorial method within the me object (the current object - think of "me" like the "this" pointer in C++) passing a parameter value of num to the method. As you can see, methods may modify parameters.

- o As you can see, a method may optionally return a value.
- Expressions:
 - Expressions are written in the fix hotelland before the fix to the control of the c
 - An expression may refer to constants, variables and other sub-expressions, and it may call methods within the current object or other objects.
 - An expression may also be used to instantiate anew object (we'll see this later)
- Control Flow: CITAIT.
 - A while loop has a boolean expression as its condition (which it uses to decide whether to run its body) and a single statement as its body. To sequence multiple statements in a while body, wrap them in a pop-level "begin" statement.
 - The begin statement lets you run one or more sub-statements in order.
 - The return statement lets a method return a value to its caller, and immediately terminates the current method.
 The return statement lets a method return a value to its caller, and immediately terminates the current method.

Now that you have a flavor for the language, let's dive into the details.

How To Buil程序,作写电话做 CS编程辅导

When you build an interpreter, you have to represent all of the elements of the interpreted language (e.g., Brewin) using classes/objects in the "host" language that you're using to build the interpreter (e.g., I , if our interpreted language:

- has variables (their name, the host language to represent variables
- has values, we have a same as a same as a same and the currer and
- has functions as as in the host language to represent a function (its name, parameter variables, and statement(s) that make up its body).
- has statements, then we may want to have class(es) in the host language to represent
 the different types of statements in the interpreted language ("while" statements, "if"
 statements, "set" statements, return" statements, etc.)
- has classes, then we'll likely have a class in the host language to represent a class in the interpreted language (holding the class's name, its fields and their initial values and its methods).
 Assignment Project Exam Help
- has objects (instantiated from classes), then we'll likely have a class in the host language to represent instantiated objects (e.g., what fields/member variables the object has and what heir current values are what methods does the object have, etc.).

As your interpreter interprets a Brewin program, if the interpreted program defines a new Brewin class, then your python program will need to create a new python object to represent/track that class. If a statement in your interpreted program instantiates a new Brewin object, then your python program will need to create and track a new python object that represents that Brewin object and the methods/fields it holds. If a statement in your interpreted program defines a new variable, then your python program will need to create and track a new python object that represents that Brewin variable. And so on:

We'll also need to have an overall Interpreter class in the host language (python) that can use all of the classes above to implement the interpreter. For this project, you MUST create a new class called *Interpreter* and derive it from our InterpreterBase class (found in our provided intbase.py). Your Interpreter class MUST implement at least the constructor and the run() method that is used to interpret a Brewin program, so we can test your interpreter (more details on this later in the spec). You may add any other public or private members that you like to your Interpreter class.

How should your Interpreter class's run() method work? Here's some pseudocode:

```
class Interpreter(InterpreterBase):
   def run(self, program):
     # parse the program into a more easily processed form
     result, parsed program = BParser.parse(program source)
```

```
if result == False
         self.__discover_all_classes_and_track_them(parsed_program)
                          find definition for class("main")
         class def
                                  te object()
         obj.run
                                  nich represents a Brewin class) look like?
And what might a Cla
class ClassDefini
  # constructor f
  def __init__(self, ...):
                           nat: cstutorcs and instance of it
  # uses the definiti
  def instantiate object(self):
    obi = ObjectDefinition()
    for method in Assignment Project Exam Help
      obj.add_method(method)
    for field in self.my fields:
      obj.add_fieldine (tufield cirita-1863) com
    return obi
And what might an Object Definition class Awhich represents a Brewin object, which may be
instantiated from a Brewin class during interpretation of a Brewin program) look like?
class ObjectDefinition:
  def __init__(selfttps://tutorcs.com
  # Interpret the specified method using the provided parameters
  def call_method(self, method_name, parameters):
    method = self. find method(method name)
    statement = method.get top level statement()
    result = self.__run_statement(statement)
    return result
  # runs/interprets the passed-in statement until completion and
  # gets the result, if any
  def __run_statement(self, statement):
   if is a print statement(statement):
     result = self. execute print statement(statement)
   elif is an input statement(statement):
```

```
result = self.__execute_input_statement(statement)
elif is_a_call本中tempt(statement)
  result = self. __execute_call_statement(statement)
elif is a while statement(statement):
  result = sel
                                statement(statement)
elif is_an if
  result = sel
                               atement(statement)
elif is_a retu
                              ement):
  result = se
                                 statement(statement)
elif is a begi
  result = sel
                               ub_statements_of_begin_statement(statement)
return result
```

The above examples will hopefully help you to get started on your implementation. These are just suggestions - you may implement your interpreter in any way you like so long as it is capable of passing our test cases and meets the explicit requirements stated in this spec.

Assignment Project Exam Help

Our Parser 程序代写代做 CS编程辅

To make things easier for you, we're going to provide you with a simple class, called BParser, that can take Brewin source code, passed in as a Python list of strings, and output a te the need for you to write your own parsing logic and fully-parsed list of stri let you focus on the le Here's how our parser class may be used:

```
# imports BParser class from bparser.py
from bparse
def main():
                         vided to your interpreter as a list of
  # all pro
 # python strings, just as shown here.
  program_source = ['(class main',
                   h method maith (tho)
                       (print "hello world!")'.
                   ') # end of method',
             ssignment Project Exam Help
 # this is how you use our BParser class to parse a valid
 # Brewin program into python list format.
 result, parsen program filtersper par (sel program _source)
  if result == True:
   print(parsed_program)
               g failed There must have been a mismatched
parenthesis.')
          https://tutorcs.com
main()
```

The above program would print the following out:

```
[['class', 'main', ['method', 'main', [], ['print', '"hello world!"']]]]
```

Notice that our parser removes extraneous spaces and newlines, and eliminates comments. You're left with a simple python list of lists that can be easily processed to build your interpreter. e.g.,

```
for class def in parsed program:
 for item in class def:
    if item[0] == 'field':
      # handle a field
    elif item[0] == 'method':
      # handle a method
```

In addition, our parser attackers a new member variable to every the perfect the perfect called line_num. You can use this to determine what line number each token was found on in the input program. For example, here's a function that prints the line numbers of all the tokens in the above program:

For our above program this would print out: CStutorcs

```
class was found on line 0
main was found on line 0
method was found on line 1
print was found on line 1
print was found on line 2
"hello worlE" was found on line 2
```

You can use the line_num field to output specific error messages (e.g., "trying to dereference a null object reference on line 5.") which will help with debugging. $\frac{149389476}{6}$

Brewin v1 L程序的写代做 CS编程辅导

The following sections provide detailed requirements for the Brewin v1 language so you can implement your interp

Formatting

- formatting (spacing, etc.) since: You need not
 - ass to parse all Brewin programs
 - aranteed to be formatted correctly and syntactically correct

WeChat: cstutorcs Classes

Every Brewin program consists of one or more classes. This section describes the syntax of defining a class as well as the requirements full mustifulfill it supporting classes in vote 10 interpreter.

Overall Class Delimonail: tutorcs@163.com

Class Definition Syntax

QQ: 749389476
Here's the syntax for defining a class:

```
(class class name ps://tittorcs.wiGOM) later in this doc
  (method ...)
                 # specific syntax will follow later in this doc
  (field ...)
  (method ...)
   # end of class definition
```

Class Definition Requirements

You must meet the following requirements when supporting classes in your interpreter.

Every Brewin program must have at least one class called main, with at least one method named main in that class. This is where execution of your Brewin program begins.

- Brewin programs may have zero or more additional classes beyond the main class
- Every Brewin days must have alleast one to thou define my truit it if I = 1
- Every Brewin class may have zero or more fields defined within it
- Class names are case sensitive, and must start with an underscore or letter, and may have underscore and must start with an underscore or letter, and may
- Classes may er within your source file; all classes are visible to all other classes and a new object) regardless of whether they're define above or belo antiation
- Methods and Methods and Methods and fields are visible to in the class regardless of the order they are defined
- There are no process of the structure of the structure
- Duplicate class names are not allowed. If a program defines two or more classes with the same name you must generate an error of type ErrorType.TYPE_ERROR by calling InterpreterBase.error(). Dat. CSTULOTCS

Class Definition Examples ignment Project Exam Help

Here are a few examples showing how to define valid Brewin classes:

```
mail: tutorcs@163.com
  (field name "")
  (field age 0)
               h:a)749389476
  (method \n/t
     (begin
       (set name n)
       (sehteps://tutorcs.com
  (method talk (to_whom)
     (print name " says hello to " to_whom)
  )
)
(class main
(field p null)
(method tell_joke (to_whom)
   (print "Hey " to whom ", knock knock!")
(method main ()
  (begin
     (call me tell_joke "Matt") # call tell_joke in current object
```

```
(set p (new person)) # allocate a new person obj. point p at it

(call pinit sidarts 150 # call line object pointed to by p

(call p talk "Paul") # call talk in object pointed to by p

)

)
)
)
```

Class Fields

This section details h ______e., member variables) inside of classes.

Field Syntax

Here's the syntax for defining Chat: cstutorcs

(field field name initial_value)
Assignment Project Exam Help

- Field names are case sensitive and must start with an underscore or letter, and contain letters, underscores and numbers.
- All fields in Brewin are private by default and may only be accessed by methods in the same object. An object cannot access the fields of another object, even if the objects are both of the same type/class.
- Fields are visible to all methods within the current object, whether those methods are defined above or below the field's definition, just like in C++.
- Fields do not have a particular type they can be assigned to a value of any type, and may be reassigned to values of different types over time.
- All field definitions must specify an initial value for the field. Valid initial values must be constants: integers like 10 or -20, true, false, null, and "strings" in double quotation marks. Expressions are not allowed to be used for the initial value of a field.
- When an object is instantiated in your program from a class, the object gets a copy of each of the fields defined in the class, with each field's value initialized to the specified initial value for that field.
- If a given class has two or more fields with the same name, you must generate an error of type ErrorType.NAME ERROR by calling InterpreterBase.error().
- None of the programs we test you with will use "me" as the name of a field. You can treat that as undefined behavior.

Field Examples

Here are some examples of field definitions:

Class Methods

This section details h

Defining Methods

Method Definition SynWeChat: cstutorcs

Here is the syntax for defining a method within a class:

Assignment Project Exam Help

(method method_name param_name1 param_name2 ... param_namen)

(statement_to_execute)

) # end of method .1 ... (C) 1 ...

end of Email: tutores@163.com

Where there may be zero or more parameters to a function. Notice that in Brewin v1, you do not specify the types of the parameters or the return type of the method. Each method has a single high-level statement to 10^{10} . 10^{10} . 10^{10} .

Method Definition Requirements

- Every class must have at least one method
- Each method definition specifies the method's name, its list of parameters if any, and a single, top-level statement to run for the method
- All formal parameters to a function must have unique names, i.e. two parameters to a function cannot have the same name. You can treat this as undefined behavior.
- We will not test you on methods with formal parameters named "me". You can treat this as undefined behavior.
- Methods in Brewin v1 do not have types for the parameters nor do they have return types. So any type of variable can be passed to a method's parameter, and any type of value may be returned (including no value at all).
- All methods are public in Bruin there are no private methods
- Methods may optionally return a value
- If a method wishes to run multiple statements, then you must specify a begin statement as the method's top-level statement. You may then have any number of sub-statements run as part of the begin statement.

• If a method has a parameter whose name is the same as the name of a field in the class, then all references to the name of the dame of the class, then all references to the parameter rather than the field (i.e., the parameter hides the field within that method). This is called shadowing. For example:

• If a given class has two or more methods with the same name, you must generate an error of type ErrorType.NAME_ERROR by calling InterpreterBase.error().

WeChat: cstutorcs

Method Definition Examples

Here are a few examples igniment Project Exam Help

Calling Methods

Syntax

Method calls use the following syntax:

```
(call target object method name param1 ... paramn)
```

where target_object can be a member variable that holds an object reference or the "me" keyword, which indicates that the call should be directed to a method in the current object that's making the call.

Requirements

程序代写代做 CS编程辅导

• You may pass any variable, constant or expression as parameters to a method call. For example, this would be a valid function call if some_method accepts a single parameter:

- Brewin v1 does not support overloaded methods (e.g., two methods with a different set of parameters). You are NOT responsible for supporting overloading or detecting invalid use of overloading, and will not be provided with any test cases that use overloaded methods.
- If a call is made as Singelined nethod you this joint in errox by lating the CIP Interpreter Base.error() method with an error type of Error Type. NAME_ERROR.
- If a call is made to a method with the wrong number of parameters, you must report an error by calling the interpreter pase error method with an arror type of Error Type. TYPE ERROR.

Examples

QQ: 749389476

The following code shows several method calls within the same and to different objects:

```
(call p init "Siddarth" 25) # calling method in other object (call park by an "5" (call p get_age))

(print "Siddarth's age is " (call p get_age))

)

)

(call p init "Siddarth" 25) # calling method in other object (call p get_age)

(print "Siddarth's age is " (call p get_age))
```

Constants

程序代写代做 CS编程辅导

Constants in Brewin are just like those in other languages.

ring constants enclosed in "double quotes", boolean You can have ich is used to designate an invalid object reference). constants (tru There are no

Integer consta or negative (e.g., -5 with no spacing between the minus sign ar have any valid integer value representable by a python intege

Here are some example constants:

- "this is a test" WeChat: cstutorcs
- -12345678901234
- 42
- true

Assignment Project Exam Help false

- null

Email: tutorcs@163.com

QQ: 749389476

Expressions

An expression is made up of constants, variables, and operations (e.g., +, -, <, ==, function calls, object instantiation) which yield a result/output value. An expression may have nested sub-expressions. An statement! For example:

- A constant (e.g., 5, "foobar", true/false, null)
- A variable name (e.g., years_old)
- An arithmetic expression, Middany of the following operators: +, -, *, /, %, e.g.:
 - o (set var (+ var 15))

The arithmetic operators must yield an integer result

• A comparison expression that compares in larger with any of the following of the followin

```
o (if (> some_int_var1 5) (print "bigger"))
```

The comparison operators must yield a boolean result

- A concatenation explains that the formation of strings and could in a new string, using the + operator:
 - o (set var (+ "foo" some var that refers to a string))
- A comparison expression that compares tripigs, with any of the following operators: ==, !=, <, >, <=, >=, e.g.:

```
o (if (>= string_var1 "foobar") (print "bigger or equal"))
```

All comparison operators compare strings lexicographically

The comparison operators must yield a boolean result

• A comparison expression that compares booleans, with any of the following operators: !=, ==, & (logical AND), | (logical OR), e.g.:

```
o (if (== boolean var1 true) (print "it's true"))
```

The comparison operators must yield a boolean result

A comparison expression that compares objects with null, with the following operators:
 ==, !=, e.g.:

```
o (if (== x null) (print "it's true"))
```

We will always compare with null, not another object.

• A boolean unary NOT expression, with the ! operator, e.g.:

```
o (if (! boolean var1) (print "the variable is false"))
```

The unary NOT operator must yield a boolean result

- A method call expression that calls a method in the current object or another object, e.g.:
 - o (set result (call me factorial num))
 - o (set result (call some_other_obj some_other_member_func 10))

• A new expression which instantiates a new object of the specified class's type and returns an object reference to the previous constant of the specified class's type and clas

Note: In Brewin, there is no *delete* command like in C++. Brewin may rely upon Python's garbage collegation and a solution of the solution of

Here are requiremen

- All expression prefix notation with spaces separating each token in the expression (all target_object method_name param)
- The types of all values used in an expression must be compatible, e.g., you can't add a string and an integer, or compare a boolean and an integer. If the types do not match, you must generate an error by calling InterpreterBase error() with a type error of ErrorType.TYPEVERRORILAT. CSTUTOTCS
- If an operator is not compatible with an operand, then you must generate an error by calling InterpreterBase_error() with a type error of ErrorType.TYPE_ERROR.
- If an expression refers to plass name fiel to parameter that does provided the superior of must generate an error by calling InterpreterBase.error() with a type error of ErrorType.NAME_ERROR.

call expression details ail: tutorcs@163.com

You may include a method call within an expression. Its usage is as follows:

(call target_object method_name arg1 arg2 ... argn)

Where there may be are a currents to so for example, the call expression could be used as follows:

```
(print num " factorial is " (call me factorial num))
```

For detailed requirements for method calls, please see the *Calling Methods* section above and the *call statement* section later in this spec.

new expression details

The new expression instantiates a new object of the specified class type, and returns an object reference to that object. It's usage is as follows:

(new class name)

For example:

(class main程序代写代做 CS编程辅导 (field other null) (method main () (begin (set (call (call (call (call (call (class other_class (field a 10) (method fower Christ: (+cstuttorcs))

In the above example, the line marked HERE instantiates a new other class object using the new expression, and the set of the line marked HERE instantiates a new other class object using the new expression, and the set of the line marked HERE instantiates a new other class object using the new expression, and the set of the line marked HERE instantiates a new other class object using the new expression, and the set of the line marked HERE instantiates a new other class object using the new expression, and the set of the line marked HERE instantiates a new other class object using the new expression, and the set of the line marked HERE instantiates a new other class object using the new expression.

Requirements:

- The new expression must be able to instantiate any class in the program, whether it is defined before or after the method that performs the new expression. See the example above, where the definition of other class is defined below the (new other_class) expression. This depail. 749389476
- If the class name is unknown, you must generate an error of type ErrorType.TYPE_ERROR by calling InterpreterBase.error().

Statements

程序代写代做 CS编程辅导

The sections below detail the types of statements that you must support in your interpreter.

begin statement

The begin statement bodies, if statements statement, if you war their top-level statement.

or more sub-statements in sequence. Since method rewin are only allowed to have a single top-level statements, you have to use a begin statement as or more sub-statements as you like inside the begin

• Syntax: WeChat: cstutorcs

```
(statement)
(statement)
(statement)
(statement)

(statementn)

Email: tutorcs@163.com
```

Example usage:

```
O: 749389476
(class main
 (field \times 0)
 (method main ()
   (begin https://tutorcs.com
     (print "hello")
     (print "world")
     (print "goodbye")
 )
)
(class main
 (field x 0)
 (method main ()
   (if (== \times 0)
     (begin
                       # execute both print statements if x is zero
       (print "a")
       (print "b")
```

y 程序代写代做 CS编程辅导

Requirements
 A beging the statement of it

The call statement per like of the lateral to a method within the current object or to a method in another object that is reference by an object reference variable. All parameters are passed by value, so changes made to the parameters in the called method must make no changes to variables passed from the current method. If the called method returns a value, then the call may be used inside an expression at: CSTUTOTCS

Syntax:

(call me method_name param1 ... paramn)# call method in other object

Email: tutorcs@163.com

• Example usage:

```
(class mai QQ ... 749389476
  (field result 0)
  (method main ()
   (beginhttps://tutorcs.com
     (call me foo 10 20)
                         # call foo method in same object
     (set other (new other_class))
     (call other foo 5 6) # call foo method in other object
     (print "square: " (call other square 10)) # call expression
   )
  (method foo (a b)
  (print a b)
  )
)
(class other class
  (method foo (q r) (print q r))
  (method square (q) (return (* q q)))
)
```

- · Requirements程序代写代做 CS编程辅导
 - A call statement must always specify a valid object reference or the "me" keyword, which is like "self" or "this" and refers to the current object
 - o Call st de to any method in the same object, whether the method in the same object, whether the below the call statement.
 - Call st Call st Call st Call statement.
 - There arguments passed in a call statement, and all arguments method name.
 - Argum 1. Constants, variables or expressions.
 - All arguments are passed by value to the called method.
 - o If the called function returns a value, then the call will evaluate to that return value and its result can be used within an expression.
 - A call made to an object reference of hull must generate an error of type ErrorType.FAULT_ERROR by calling InterpreterBase.error().
 - A call made to a method name that is not defined for the target object must generate as ground from the property of the proper
 - A call made to a method with the wrong number of parameters must generate an error of type Error Type. TYPE ERROR by calling Interpreter Base. error().
 Email: tutorcs with a calling Interpreter Base.

if statement

Used to perform an if Orose operation. 389476

Syntax - there are two variations:

```
https://tutorcs.com
(if expression (run_if_expr_is_true))
(if expression (run_if_expr_is_true) (run_if_expr_is_false))
```

Example usage:

```
(class main
  (field x 0)
  (method main ()
      (begin
          (inputi x) # input value from user, store in x variable
      (if (== 0 (% x 2))
          (print "x is even")
          (print "x is odd") # else clause
      )
      (if (== x 7)
```

```
(print "lucky seven") # no else clause in this version
) 程序代写代数 CS编程辅导
(if true (print "that's true") (print "this won't print"))
)
```

Requirements

)

- o You me nent works like an if or if/else statement in any langue
- o If the (ement does not evaluate to a boolean type, you must generate an error of type ErrorType.TYPE_ERROR by calling InterpreterBase.error().

inputi and inputs statements at: cstutorcs

Used to input either an integer (input) or a string (inputs) from the user or automate it lesting framework.

Syntax:

```
Email: tutorcs@163.com
```

(inputi variable) # sets variable to the user-provided integer value
(inputs variable) # sets variable to the user-provided string value

• Example usage Q: 749389476

- Requirements:
 - Your implementation MUST use our InterpreterBase.get_input() method to read input from the user (so we can do automated testing).
 - The inputi/inputs statement must update the specified variable to the value that was typed in by the user.
 - You do NOT need to handle the case where the user types an invalid input (e.g., the user types "abc" when input is called and expects an integer)

程序代写代做 CS编程辅导

print statement

Used to print values (print values

• Syntax:

(print arg1

Where the arguments inay be integer, string and boolean constants, variables referring to integer, string or boolean values, or expressions which evaluate to integer, string or boolean values. You will not be asked to print object references or null.

WeChat: cstutorcs

Example usage:

```
(class main Assignment Project Exam Help (method main spignment " (* 3 5) " and here's a boolean" true)

(print "here's a result " (* 3 5) " and here's a boolean" true)

Email: tutorcs@163.com
```

which prints:

here's a result QQ: 749389476

- Requirements:
 - The print to print it using our Interpreter Base.output() method.
 - Your implementation MUST use our InterpreterBase.output() method to actually output data to the user (so we can do automated testing).

return statement

Used to terminate the current method's execution and optionally return a value.

Syntax - there are two variations:

· Example usage: 程序代写代做 CS编程辅导

```
(class main
  (method foo (q)
                       eturns the value of 3*q
    (retur
  (method
)
(class main
  (method foo (q)
    (while (> q 0)
       (iWfe(hat) cstutorcs loop and function foo
         (set q (- q 1))
          Assignment Project Exam Help
    )
  )
  (method main ()
    (print Ethail: tutores@163.com
)
```

- Requirements QQ: 749389476
 - The return statement must terminate the current method immediately, including breaking out of all (nested) while loops, begins, and if statements.
 - o If the return statement the function but does not return a value to the calling function.
 - o The returned value may be of any type

set statement

The set statement sets the value of a member variable (aka field) or a method's parameter to a specified new value.

Syntax:

```
(set field_name value)
(set parameter_name value)
```

Where value can be a constant, a field name, a parameter name, or an expression.

· Example usag程序代写代做 CS编程辅导

```
(class person
  (field n
  (field a
                          (set name n) (set age a)))
  (method
                          rint name " says hello to " to whom))
  (method
)
(class main
 (field x 0)
 (method foo (q)
   (begin WeChat: castute
                                       d to integer constant
    (set q true)
                           # setting parameter to boolean constant
                           # setting field to a string constant.
    (set x "foobar")
    (set xASSI211111CHTetHISOICTO ESXIAMEXITEGION
                           # setting field to refer to new object
    (set x (new person))
                           # setting field to null
    (set x null)
          Email: tutorcs@163.com
 (method main ()
   (call me for
               5: 749389476
 )
)
```

- The set statement changes the value of the specified field or parameter.
- In Brewin v1 it is allowed to assign a variable a value of a different type than the variable referred to prior to the assignment.
- We will not test assignment of the "me" object reference, so you may handle this (or not handle it) in any way you like:

```
(set me something) # we won't test this!
```

- If a set statement attempts to assign a non-existent field or parameter to a value then you must generate an error of type ErrorType.NAME_ERROR by calling InterpreterBase.error().
- We will not test you with a set statement that attempts to set a variable to the result of a function call (or any expression) that doesn't return a value. You can treat this as undefined behaviour.

while statement

程序代写代做 CS编程辅导

Used to perform a while loop operation.

```
Syntax:
                       to_run_while_expression_is_true)
  (while expr
  Example usag
  (class main
   (field x 0)
   (method main ()
     (begin WeChat: cstutorcs
      (inputi x)
      (while (> \times 0)
         egi Assignment Project Exam Help
       )
          Email: tutorcs@163.com
   )
          QQ: 749389476
  )
```

- Requirements:
 - Make it work like a while loop in any language
 - The while top shody buttle a tingle tratement. If you wish to have multiple statements run in the while loop, you must use a begin statement as the while loop's body
 - If the condition of the while loop does not evaluate to a boolean type, you must generate an error of type ErrorType.TYPE_ERROR by calling InterpreterBase.error().

Things We Will and Work Test You CS编程辅导

Your may assume the following when building your interpreter:

WE WILL NO
 You m
 You m
 Indicate the syntax errors of any type ograms that we present to your interpreter will be syntax
 There
 All stall 12

RPRETER ON SYNTAX ERRORS OF ANY TYPE ograms that we present to your interpreter will be syntax errors. That means:

 There
 All stall 12
 There of the syntax errors of any syntax errors of any type of the syntax errors. That means:
 There of the syntax errors of any type of the syntax errors of any type of the syntax errors. That means:
 There of the syntax errors of any type of the syntax errors of any type of the syntax errors.

- All stall and formed and not missing syntactic elements; for example and ments is guaranteed to have at least a condition and a statement to execute if the condition is true
- All variable names will start with a letter or underscore (not a number)
- Note: if you do add checks for syntax errors, you're much more likely to save debugging to nat: CSTUTOTCS
- WE WILL TEST YOUR INTERPRETER ON ONLY THOSE SEMANTIC and RUN-TIME ERRORS EXPLICITLY SPECIFIED IN THIS SPEC
 - You man NOT assume that all programs presented to your interprete will be semantically correct, and must address those errors that are explicitly called out in this specification, via a call to InterpreterBase.error() method.
 - out in this bearies ion but this for failing to address errors that aren't explicitly called out in this bearies ion but this for failing to address errors that aren't explicitly called
 - o Examples of semantic and run-time errors include:
 - Operations on incompatible types (adding a string and an int)
 - Using non-box ear expessions nat/while loop conditions
 - Fassing an incorrect number of parameters to a method
 - Referring to a class name, method name, field or parameter that has not been defined
 - Direction that the ference is a method via an object reference field or parameter whose value is currently null.
 - You may assume that the programs we test your interpreter on will have AT MOST ONE semantic or run-time error, so you don't have to worry about detecting and reporting more than one error in a program.
 - You are NOT responsible for handling things like divide by zero, integer overflow, integer underflow, etc. Your interpreter may behave in an undefined way if these conditions occur. Will will not test your code on these cases.
- WE WILL NOT TEST YOUR INTERPRETER ON EFFICIENCY, EXCEPT: YOUR
 INTERPRETER NEEDS TO COMPLETE EACH TEST CASE WITHIN 5 SECONDS
 - It's very unlikely that a working (even if super inefficient) interpreter takes more than one second to complete any test case; an interpreter taking more than 5 seconds is almost certainly an infinite loop.
 - o Implicitly, you shouldn't have to *really* worry about efficient data structures, etc.

Coding Requiremen 代写代做 CS编程辅导

You MUST adhere to the following coding requirements for your program to work with our testing framework, ar and the following coding requirements for your program to work with our testing framework, ar and the following coding requirements for your program to work with our testing framework, are an analysis above a zero on this project:

- Your Interpret
 You must deri
 class

 Class
 The control of the contro
- Your Interpreter class constructor (__init__()) must start with these two lines in order to properly initialize our base class:

```
def __init__(self, console_output=True, inp=None, trace_output=False):
    super().__init__(console_output, inp) # call InterpreterBase's constructor
```

The inp parameter is used for our testing scripts. It's the way we pass input to your program in an automated manner of the constructor and otherwise ignore it. So the way we pass this field onto Interpreter Base's constructor and otherwise ignore it.

The *trace_output* parameter is used to help in your debugging. If the user passes True in for this, you programs how the purpur programs from the purpur programs from the screen. We will not test you on this, but it will be helpful for debugging. For example:

```
class Interpreter(InterpreterBase):
    ...
    def interpret_statement(self, statement, line_num):
        print(f"{line_num}: {statement}")
        ... # your code to interpret the passed-in statement
```

 You must implement a run method in your Interpreter class. It must have the following signature:

```
def run(self, program):
   ...
```

Where the second parameter, program, is an array of strings containing the Brewin program text transverse want to interpret e.g. (大) 大主 捕

- When you pring the transfer "blah")) your interpreter must use the InterpreterBase.output() method, to ensure that your program's output can be evaluated by our test scripts. By default, our output() method will display all output to the screen, but during automated grading we will redirect the output for testing. YOU MUST NOT USE python's print() statement to print output as we will not process this data in our testing framework.
- When you get input from the user (e.g., for an inputi/inputs statement) your interpreter must use the Interpreter Base of the passed in by our test scripts. By default, our get_input method will prompt the user via the keyboard.
- To report errors te a typing errors, name errors unitime errors, and optionally syntax errors if you like you must call the interpreterBase.error() method with the specified error:

• We define all of the keywords for the Brewin language in our InterpreterBase class, e.g.:

```
# constants
CLASS_DEF = 'class'
METHOD_DEF = 'method'
FIELD_DEF = 'field'
NULL_DEF = 'null'
BEGIN_DEF = 'begin'
SET_DEF = 'set'
...
```

You MUST use these constants in your interpreter source file rather than hard-coding these strings in your code.

You must name your interpreter source file interpreterv1.py.

You may submit as many other supporting Python modules as you like (e.g. class.py, method.py,) which are used by our niterogeter (1,0) 的 大工 中

• Try to write self-documenting code with descriptive function and variable names and use

idiomatic Python code.

 You MUST No vour code de this project.

e.py file since you will NOT be turning this file in. If d intbase.py file, this will result in a grade of zero on

Deliverables 程序代写代做 CS编程辅导

For this project, you will turn in at least two files via GradeScope:

- Your interpret
 A readme.txt
 issues/bugs in your program (or, "all good!")
- Other python your created to support your interpreterv1.py module (e.g., environ)

We will be grading your solution on Python 3.11. Do not use any external libraries that are not in the Python standard library at: CSTUTOTCS

Whatever you do, make sure to turn in a python script that is capable of loading and running, even if it doesn't fully implement all of the language features. We will test your code loading the fifty test cases, so you can get substantial credit even if you don't implement the full language specification.

The TAs have created a length cithur to stock shadon and in the sound a parser bparser.py) as well as a brief description of what the deliverables should look like.

Grading QQ: 749389476

Your score will be determined entirely based on your interpreter's ability to run Brewin programs correctly (however your points for points for points for points for points for points for program that doesn't run with our test automation framework will receive a score of 0%.

The autograder we are using, as well as a subset of the test cases, is publicly available on GitHub. Other than additional test cases, the autograder is exactly what we deploy to Gradescope. Students are encouraged to use the autograder framework and provided test cases to build their solutions. Students are also STRONGLY encouraged to come up with their own test cases to proactively test their interpreter.

We strongly encourage you to write your own test cases. The TAs have developed a tool called <u>barista (barista.fly.dev)</u> that lets you test any Brewin code and provide the canonical response. In discussion, TAs will discuss how to use our test infrastructure and write your own test cases.
